A brachial plexus injury (BPI), also known as brachial plexus lesion, is an injury to the brachial plexus, the network of nerves that conducts signals from the spinal cord to the shoulder, arm and hand. These nerves originate in the fifth, sixth, seventh and eighth cervical (C5-C8), and first thoracic (T1) spinal nerves, and innervate the muscles and skin of the chest, shoulder, arm and hand.

Brachial plexus injuries that occur at the level of the spinal cord often produce greater pain than injuries more distant from the spinal cord. In addition, injuries nearer the spinal cord may cause a burning numbness, which is called paresthesias or dysesthesias.

Brachial plexus injury can induce severe neurologic deterioration, leading to paralysis of the arm and hypohesia, which can interrupt daily activities and function. Thus, clinicians need to be aware of the possible mechanisms of injury and should attempt to pinpoint the location of injury in order to plan the best therapeutic strategy.
