

# Catecholamines Physiology Pharmacology And Pathology For Students And Clinicians

Covers fundamental aspects of catecholamine biology, as well as physiology, pathophysiology, pharmacology, and tumors of the sympathoadrenal system. Provides easily understood, concise coverage of difficult concepts, all in one convenient volume.

Chromaffin cells (CCs) of the adrenal gland and the sympathetic nervous system produce the catecholamines (epinephrine and norepinephrine; EPI and NE) needed to

coordinate the bodily "fight-or-flight" response to fear, stress, exercise, or conflict. EPI and NE release from CCs is regulated both neurogenically by splanchnic nerve fibers and nonneurogenically by hormones (histamine, corticosteroids, angiotensin, and others) and paracrine messengers [EPI, NE, adenosine triphosphate, opioids, ...

A catecholamine is any compound with a catechol nucleus (a benzene ring with two adjacent hydroxyl groups) and an amine-containing side chain. The chemical configuration of five of the more common catecholamines in clinical use is demonstrated in Figure 15-6. The endogenous catecholamines in humans are dopamine (DA), NE, and EPI.

Low concentrations of catecholamines stimulate the heart by promoting Ca<sup>2+</sup> movements, whereas excessive amounts of catecholamines produce cardiac dysfunction by inducing intracellular Ca<sup>2+</sup> overload in cardiomyocytes. Several studies have shown, however, that under stressful conditions high concentrations of catecholamines become oxidized to form aminolutins and generate oxyradicals.
