

Digital Signal Processing A Computer Based Approach 2nd Second Edition

This course discusses concepts, algorithms and applications of Digital Signal Processing. The course materials are Introduction to DSP and Sampling Theory, Discrete-Time Systems, Digital Filters and Spectral Analysis. The materials are delivered in video presentation and the total

duration for finishing all materials is about two hours.

Based on Sanjit Mitra's extensive teaching and research experience, *Digital Signal Processing, A Computer Based Approach*, fourth edition, is written with the reader in mind. A key feature of this book is the extensive use of MATLAB-based examples that illustrate the program's powerful capability to solve signal processing problems. An informal and easy-to-understand introduction to digital signal processing, this treatment emphasizes digital audio and applications to computer music. Topics include phasors and tuning forks, the wave

equation, sampling and quantizing, feedforward and feedback filters, comb and string filters, periodic sounds, transform methods, and filter design.

Digital signal processing (DSP) is the use of digital processing, such as by computers or more specialized digital signal processors, to perform a wide variety of signal processing operations. The digital signals processed in this manner are a sequence of numbers that represent samples of a continuous variable in a domain such as time, space, or frequency.

Digital signal processing - Wikipedia

A digital signal processor is a fast special-purpose microprocessor with architecture and instruction set designed specifically for efficient implementation of digital signal processing algorithms. Digital signal processors are used for a wide range of applications, from communications and control to speech and image processing.

Data transmission and data reception (or, more broadly, data communication or digital communications) is the transfer and reception of data (a digital bitstream or a digitized analog signal) over a point-to-point or point-to-multipoint communication channel. Examples of such channels are copper wires, optical fibers, wireless communication channels, storage media and computer buses.

This chapter is a crash course in digital filter piloting. In the first section of this chapter we discuss technicalities relating to computing convolutions in the time domain. The second section discusses the circular convolution and how it can be used to filter in the frequency domain; this is frequently the most efficient way to filter a signal.
