

New Liver Anatomy Portal Segmentation And The Drainage Vein

[Liver segmentation: Practical tips - ScienceDirect](#)

Anatomical arguments: hepatic vein segmentation must be added to portal segmentation: the academic left lobe is the left hepatic vein sector, and the left hepatic fissure separates the classical right and left lobes. Portal vein segmentation must be preferred: portal vein duplication of branches of first order occurs only in 23.5% of the cases, while arteriobiliary duplication of first-order branches is noted in 50% of the livers, portal segmentation being much simpler.

A new era for liver anatomy has dawned. With the development of multidetector row computed tomography (MDCT) in the 1990s, precise volume-rendered 3-D images could be constructed, leading to new observations. Liver anatomy has since been reevaluated from the standpoint of portal segmentation and drainage veins and includes a reclassification of the liver.

[New Liver Anatomy - Portal Segmentation and the Drainage](#)

As mentioned above, portal embolisation consists of embolising the portal branches of the liver that will be removed about 4 weeks before the surgery, in order to increase the volume of the liver left in place, by redistribution of the portal blood flow . . . Portal anatomic variations increase the complexity of this procedure.

[Liver segmentation: Practical tips - ScienceDirect](#)

The portal vein divides the liver into upper and lower segments. The left and right portal veins branch superiorly and inferiorly to project into the center of each segment. On a frontal view of the liver the posteriorly located segments VI and VII are not visible.
