Symmetries in various forms pervade mathematics and physics. Globally, there are the symmetries of a homogenous space induced by the action of a Lie group. Locally, there are the infinitesimal symmetries induced by differential operators, including not only those of first order but of higher order too.

In mathematics, a system of equations is considered overdetermined if there are more equations than unknowns. An overdetermined system is almost always inconsistent when constructed with random coefficients. However, an overdetermined system will have solutions in some cases, for example if some equation occurs several times in the system, or if some equations are linear combinations of the others. The terminology can be described in terms of the concept of constraint counting. Each unknown can

Lie's algorithm for calculating these groups is well known: the (otherwise intractable) symmetry condition is linearized to obtain an overdetermined system of linear homogeneous 'determining equations' for the group generators. However, the size and complexity of this system can make solving it impractical.

An example of this kind of systems is given by the "determining equations" which arise when one imposes the linearized symmetry condition on the differential equation(s) under study.

In mathematics, a system of linear equations or a system of polynomial equations is considered underdetermined if there are fewer equations than unknowns (in contrast to an overdetermined system, where there are more equations than unknowns).The terminology can be explained using the concept of constraint counting.Each unknown can be seen as an available degree of freedom.

Symmetries of ordinary di?erential equations are used for reduction of order and complete in- tegration, as well as for the construction of invariant solutions ( [1], Chapter 3). Symmetries of partial di?erential equations yield reductions of order and/or number of variables.
