

The Neuronal Codes Of The Cerebellum

The Neuronal Codes of the Cerebellum provides the most updated information on what is known on the topics of the cerebellum’s anatomy and single cell physiology, two areas where there has been a gap in knowledge regarding the specific codes it uses to process information internally and convey commands to other brain regions. This has created difficulties for researchers and clinicians looking to develop an understanding of the mechanisms by which it contributes to behavior and how its ... A completely different question, however, is whether neurons transmit information by using any of these quantities as a neural code. In this section we critically review the notion of rate codes, and contrast rate coding schemes with spike codes. 7.6.1 Limits of rate codes.

Neural coding is a neuroscience field concerned with characterising the hypothetical relationship between the stimulus and the individual or ensemble neuronal responses and the relationship among the electrical activity of the neurons in the ensemble. Based on the theory that sensory and other information is represented in the brain by networks of neurons, it is thought that neurons can encode both digital and analog information.

The neural code is the set of rules and syntax that transform electrical impulses emitted by the neurons into perceptions, memories, knowledge, decisions, and actions. Neuroscientists try to decipher the brain’s neural codes by searching for reliable correlation between firing patterns of neurons and behavioral functions (Abbott & Sejnowski, 1999; Sanger, 2003).

To be able to support the formation of episodic memories, entorhinal cortex and hippocampal formation should contain a neuronal code that follows several requirements. First, the code should include information about position of the agent (“where”), sequence of events (“when”), and the content of the experience itself (“what”).
